EQUIVARIANT STABLE HOMOTOPY THEORY

In mathematics, more specifically in topology, the equivariant stable homotopy theory is a subfield of equivariant topology that studies a spectrum with group action instead of a space with group action, as in stable homotopy theory. The field has become more active recently because of its connection to algebraic K-theory.

Stable homotopy theory is made to give sense to cohomology theories with a strong geometric flavour, the very fundamental ones being cobordism and K-theory. These two examples need, as an input, the notion of (equivariant) vector bundle (equivariant vector bundle over the point are the finite dimensional representations of the group).

Equivariant stable homotopy theory over some topological group G G is the stable homotopy theory of G -spectra. This includes the naive G -spectra which constitute the actual stabilization of equivariant homotopy theory , but is more general, one speaks of genuine G G -spectra .

The stable homotopy category can be obtained from the category of orthogonal spectra by formally inverting the class of π -isomorphisms. Now we get to the smash product of orthogonal spectra. We define a bimorphism $b: (X;Y) \rightarrow Z$ from a pair of orthogonal spectra $(X;Y)$ to an orthogonal spectrum Z as a collection of based $O(p) \times O(q)$ -equivariant maps $b_{p;q}: X^p \times Y^q \rightarrow Z$.

A first attempt to construct an equivariant stable homotopy theory would define the set of stable G -maps (G is finite) from X to Y to be the direct limit $\varinjlim [Z^n X, X^n Y]^G$, where the G -actions on $Z^n X$ and $Z^n Y$ are obtained by directly suspending the actions on X and Y , and $c^{-1} - 1'$ denotes G -homotopy classes of G -maps.

Akhil Mathew, Niko Naumann, Justin Noel Let G be a finite group and let \mathcal{C} be a family of subgroups of G . We introduce a class of \mathcal{C} -equivariant spectra that we call \mathcal{C} -nilpotent. This definition fits into the general theory of torsion, complete, and nilpotent objects in a symmetric monoidal stable \mathcal{C} -category, with which we begin.

Nilpotence and descent in equivariant stable homotopy theory

In mathematics, stable homotopy theory is that part of homotopy theory (and thus algebraic topology) concerned with all structure and phenomena that remain after sufficiently many applications of the suspension functor. A founding result was the Freudenthal suspension theorem, which states that given any pointed space.

From this point on, classical techniques of equivariant stable homotopy theory enter the proof. These include the Wirthmüller isomorphism, geometric fixed points, isotropy separation and the tom Dieck splitting. The central idea is to do induction on the order of subgroups and use the case of free G -spectra as the induction basis.

Rigidity in equivariant stable homotopy theory

stable homotopy theory by reading Lewis-May-Steinberger's book [LMS86] on equivariant stable homotopy theory and letting $G = *$, but this may not appeal to everyone. In any case, perhaps this isn't necessarily a good reference for nontrivial groups. Unstable equivariant questions are very natural, and somewhat reasonable.

Equivariant homotopy theory is homotopy theory for the case that a group G acts on all the topological spaces or other objects involved, hence the homotopy theory of topological G -spaces. The canonical homomorphisms of topological G G -spaces are G G -equivariant continuous functions , and the canonical choice of homotopies between these are G G -equivariant continuous homotopies (for trivial G G -action on the interval).

The stable versions of equivariant and motivic homotopy theory play important roles in the geometry of manifolds, algebraic cycles, and quadratic forms. Stable equivariant homotopy theory is the study of topological spaces equipped with a group action up to stable equivariant weak equivalence.
