Zeolite beta is an intergrowth of two or three polymorphs, including chiral polymorph-A, achiral polymorph-B, and polymorph-C. Chiral polymorph-A of zeolite beta is highly desired because of its potential applications in enantioseparation and asymmetric catalysis. However, it is still impossible to obtain the pure polymorph-A of zeolite beta.

The Charge Density Mismatch approach to zeolite synthesis has been applied to the Li-Sr-choline aluminosilicate system yielding the related structures UZM-4 (BPH) and UZM-22 (MEI). The elements of synthesis necessary to achieve template cooperation were demonstrated within the approach, including how to handle very strong structure directing agents such as Li and Sr that are not normally used in that role.

Most importantly, hierarchically structured zeolites offer an effective solution to the mass transport problem associated with conventional zeolites in catalysed reactions because they combine the catalytic features of micropores and the improved accessibility and increased molecular transport related to the addition of several porosities within a single body. In recent years, many strategies have been successfully developed to synthesize hierarchically structured zeolitic materials.
